Ferrimagnets contain some kinds of magnetic ions, the magnetic moments of which are antiferromagnetically coupled with each other as shown in Fig. 1(a). Their spontaneous magnetization originates from the difference of magnetic moments of sublattices. In some ferrimagnets, the size of the sublattice magnetic moments is balanced at a temperature called the magnetization compensation temperature \( T_M \), resulting that net magnetization vanishes. In addition, when the gyromagnetic ratio differs depending on the kind of ions, the net angular momentum becomes zero at a temperature called the angular momentum compensation temperature \( T_A \), which is considered as a key characteristic of spintronics from the viewpoint of high-speed magnetic response. While \( T_M \) can be easily measured by magnetization measurements, \( T_A \) has not been able to be measured directly as the temperature that the net angular momentum is zero. In order to detect \( T_A \), the Barnett effect was used in this work. We constructed a variable temperature apparatus for measuring the Barnett effect, and determined \( T_A \) of the ferrimagnetic insulator Ho\(_3\)Fe\(_5\)O\(_{12}\).

The Barnett effect is a phenomenon in which matter is magnetized by mechanical rotation \( \boldsymbol{\Omega} \) [1], resulting from angular momentum \( \boldsymbol{J} \) of electrons in material aligns with the rotation axis through the spin-rotation coupling \( - \boldsymbol{J} \cdot \boldsymbol{\Omega} \). The Barnett effect does not apply when the net angular momentum \( \langle \boldsymbol{J}_{\text{net}} \rangle = 0 \), which is the definition of the angular momentum compensation.

Figure 1(b) shows a schematic illustration of our experimental setup [2]. The powder sample of Ho\(_3\)Fe\(_5\)O\(_{12}\) packed in a capsule was floated by bearing air and rotated by blowing driving air on the impeller. The magnetization \( M_\Omega \) induced by mechanical rotation was detected with a fluxgate magnetic sensor through the stray magnetic field from the sample. To realize the measurement under low temperatures, the system was placed into a cryostat, and the rotor was driven by nitrogen gas cooled through a heat exchanger.

Figure 2 shows that \( M_\Omega \) becomes zero at 135 and 240 K. The former corresponds to \( T_M \) determined by conventional magnetization measurements. At \( T_M \), the angular momentum in the sample aligns with \( \boldsymbol{\Omega} \), but magnetization \( M \) is zero, resulting in \( M_\Omega = 0 \). The latter is \( T_A \). The bottom of Fig. 2 shows \( \langle \boldsymbol{J}_{\text{net}} \rangle \) obtained from \( M_\Omega \) and \( M \). At \( T_A \approx 240 \text{ K} \), \( \langle \boldsymbol{J}_{\text{net}} \rangle \) becomes zero.

We succeeded in observation of the temperature dependent net angular momentum and determination of \( T_A \) of Ho\(_3\)Fe\(_5\)O\(_{12}\) [2]. Furthermore, the gyromagnetic reversal state, where the angular momentum and the magnetization are coupling inversely in ordinary electrons, was realized at the temperatures between \( T_M \) and \( T_A \).

The Barnett effect enables us to measure the net angular momentum in materials and to determine \( T_A \), supporting to exploration of candidate materials for the high-speed magnetic devices utilizing fast-magnetization reversal at \( T_A \).
